Student Engagement and Student Learning: Testing the Linkages

Abstract

This study examines (1) the extent to which student engagement is associated with experimental and traditional measures of academic performance, (2) whether the relationships between engagement and academic performance are conditional, and (3) whether institutions differ in terms of their ability to convert student engagement into academic performance. The sample consisted of 1,058 students at 14 four-year colleges and universities that completed several instruments during 2002. Many measures of student engagement were linked positively with such desirable learning outcomes as critical thinking and grades, although most of the relationships were weak in strength. The results suggest that the lowest-ability students benefit more from engagement than classmates, first-year students and seniors convert different forms of engagement into academic achievement, and certain institutions more effectively convert student engagement into higher performance on critical thinking tests.

KEY WORDS: student engagement, critical thinking, value added, NSSE, student learning

Student Engagement and Student Learning: How Can We Characterize the Linkages?

Background

Various approaches have been used to estimate collegiate quality. For instance, some analyses focus on quantitative characteristics of institutions and programs, such as graduation rates, minority access, and faculty characteristics. Other approaches emphasize outcomes such as performance on general education and major field tests, expert judgments by accreditors (which are usually based usually on inputs and resources), and reputational ratings such as those published by *US News & World Report*. Still others employ surveys of student experiences and self-reports of their learning and personal development. Each method has advantages and limitations as well as champions and critics (Chun, 2002; Klein, 2001, 2002; Kuh & Pascarella, 2004; Pascarella, 2001).

Comprehensive assessment systems typically use multiple indicators to tap quality (Astin, 1991; Ewell, 1984, 1988; Gentemann, Fletcher, & Potter, 1994; Halpern, 1987; Jacobi, Astin, & Ayala, 1987; Ratcliff, Jones et al., 1997; Terenzini, 1989; Vandament, 1987). Student surveys are particularly popular because they are generally less expensive and easier to develop and administer than tests of student knowledge and proficiencies. When well-crafted, student surveys can provide insights into the student experience that other sources of information cannot, such as estimates of one's ability to interact effectively with others on an individual basis or in small groups, and the degree to which one's values and ethics have developed since starting college (Kuh, 2001, 2003; Pace, 1984).

A fair amount of evidence indicates that student self-reports are valid and reliable under certain conditions (Baird, 1976; Pace, 1984; Pohlmann, 1974): (1) the information requested is known to the respondents, (2) the questions are phrased clearly and unambiguously, (3) the

questions refer to recent activities, (4) the respondents think the questions merit a thoughtful response, (5) the information requested is potentially verifiable, and (6) the question asks for information that is known to those answering the questions and does not threaten, embarrass, or violate their privacy or encourage the respondent to respond in socially desirable ways.

However, even when surveys are designed to meet these conditions, as with the National Survey of Student Engagement (NSSE) (Kuh et al., 2001), it does not necessarily mean that the surveys ask about behaviors that are linked to desired outcomes, such as whether institutions that engage students at higher levels are adding value to the student experience.

Student engagement is generally considered to be among the better predictors of learning and personal development. The premise is deceptively simple, perhaps self-evident: The more students study or practice a subject, the more they tend to learn about it. Likewise, the more students practice and get feedback on their writing, analyzing, or problem solving, the more adept they should become (Kuh, 2003). The very act of being engaged also adds to the foundation of skills and dispositions that is essential to live a productive and satisfying life after college. That is, students who are involved in educationally productive activities in college are developing habits of the mind and heart that enlarge their capacity for continuous learning and personal development (Shulman, 2002). The widespread use of the NSSE survey – more than 850 different four-year colleges have used it at least once since 2000 – underscores the need to understand the degree to which – and the processes whereby – student engagement contributes to more favorable outcomes for college students.

In one recent study, using data from six South Dakota public colleges and universities, the National Center for Higher Education Management Systems (NCHEMS) found some positive links between student engagement and ACT CAAP scores, though the strength of the

statistically significant associations were modest at best (Ewell, 2002). However, the NCHEMS researchers emphasized that the measures of student engagement and the CAAP test scores were obtained at different points in time, in many instances a year or more separated the two measurement points. Other studies are more promising, such as those by Hughes and Pace (2003) and by institutional researchers at individual colleges and universities (e.g., Indiana University Bloomington, St. Xavier University, University of Montana, and the University of Wisconsin-Green Bay) who report positive relationships between NSSE results and persistence, as well as academic performance represented by college grade point average (GPA). Even so, questions remain about whether collegiate grades and tests such as the ACT CAAP are adequate measures of how much students learn, and to what degree the institution or general intellectual ability shapes GPA.

To address these questions, RAND and the Council for the Aid to Education are developing, testing and refining new measures of college-level learning. The goal is to provide richer indicators of important dimensions of student learning than are tapped by existing instruments (Klein, 2002; Klein et al., in press). By adjusting for student ability prior to matriculation (such as through SAT scores and background characteristics), it is anticipated that the new RAND measures will be more sensitive to program and institutional effects than traditional tests of general educational abilities (Bohr et al., 1994; Pascarella et al., 1994; Pascarella & Terenzini, 1991; Winter, McClelland & Stewart, 1981), thereby promising value-added estimates of institutional performance (Benjamin & Hersh, 2002).

Purposes

This study examines the forms of student engagement associated with learning as measured by the RAND tests, the new essay prompts on the Graduate Record Examination (GRE), and college GPA. More specifically, we sought to determine:

- (1) the extent to which student engagement is related to experimental and traditional measures of academic performance;
- (2) the forms of student engagement that are most closely related to student performance;
- (3) whether the relationships between student engagement and academic performance are “conditional,” or vary depending on student characteristics; and
- (4) whether certain four-year colleges and universities are more effective than others in converting student engagement into stronger academic performance.

Analytic Approach

Data Sources

The NSSE survey instrument, *The College Student Report* (hereafter, *The Report*), is composed of about 70 items that assess the extent to which students devote time and energy to educationally purposeful activities. A large majority of items from *The Report* deal with behaviors that have been linked empirically to favorable outcomes of college in prior studies (Kuh, 2001, 2003). The psychometric properties of the NSSE survey are reported in detail by Kuh et al. (2001) and at http://www.iub.edu/~nsse/html/psychometric_framework_2002.htm. NSSE results have been treated by some postsecondary institutions as a proxy for student learning, although the survey was designed primarily to provide process indicators, or measures that could help colleges and universities identify areas of student performance and institutional practices that could be improved to enhance the overall quality of the student experience (Ewell & Jones, 1996).

The measures developed by RAND consist of a series of newly developed cognitive and performance tests (Klein et al., in press). Specifically, the RAND tests consist of various combinations of six different 90-minute critical thinking and performance problems. The two performance tests were modeled after the performance section of the bar exam (Klein, 1996). The four critical thinking tests were derived from “Tasks in Critical Thinking” designed by the New Jersey Department of Education (Ewell, 1994). Subject areas for the critical thinking tasks included science, social science, and arts and humanities. In addition, RAND researchers administered two essay prompts from the GRE (Klein et al., in press). The 45-minute make-an-argument prompt asked students to take and argue a position on a topic. The 30-minute break-an-argument prompt asked students to critically analyze a given position on an issue. The RAND and GRE tasks were presented to students in open-ended formats. In addition, RAND researchers were able to obtain cumulative GPA and total SAT scores for most students in the 2002 field test.

Sample and Administration

RAND researchers administered *The Report* and their own cognitive tests to 1,352 students at 14 four-year colleges and universities during the fall and spring of 2002. Students from all four undergraduate class levels were recruited and paid \$20 to \$25 per hour of testing time as an incentive. SAT scores were not available for 149 students, paring our analytic sample to 1,203 cases. Missing student responses on other control variables reduced the analytic sample further to 1,058. Of the 1,058 students with complete data, 940 completed the RAND measures and 506 completed the GRE tests. The NSSE instrument was administered in a non-standard method. Instead of exclusively designating a portion of time to administer *The Report*, students were directed to begin the survey if they completed their open-ended written tasks before time

was called. They were then given additional time to complete the survey. It is not known what effect, if any, this administration procedure may have had on student responses.

Respondent Characteristics. The colleges that were invited to participate represented an intentional mix of institutional characteristics – public/private, urban/nonurban location, admissions selectivity, region of the country, large/small enrollments, and varied student characteristics such as race/ethnicity. Students at participating institutions self-selected themselves by responding to their university’s invitations, such as announcements in student or local newspapers. The four class levels were almost evenly represented (i.e., the sample consisted of 28, 25, 23, and 23 percent first-year students through seniors, respectively). Approximately 98 percent of participants were enrolled full-time, and about 57 percent were women. About 73 percent classified themselves as exclusively White, while 9 percent were Black, seven percent were Asian, three percent were Latina/o, and another 7 percent were multiracial. The percentage of Black respondents was bolstered by the participation of an HBCU institution. Nearly 5 percent of respondents considered themselves international students, and 8 percent had begun college at an institution other than their current one. Full-time students and international students were overrepresented compared with the universe of college students (NSSE, 2003), while transfer students were underrepresented. Ten of 14 colleges (71 percent) were private as compared with 63 percent of U.S. colleges (NSSE, 2004). To the extent that it was possible to do so with 14 colleges, the sample roughly approximated U.S. colleges with respect to region of the country, Carnegie Classification, enrollment, and urbanicity (NSSE, 2004). Klein et al. (in press) provide further details on the characteristics of participating colleges.

Measures

Student learning was assessed by academic performance as measured by the RAND and GRE test scores, and college-reported GPA. A set of engagement and self-reported outcome measures was selected from the NSSE survey for the analysis. Five of these measures are what NSSE publications have termed “clusters of effective educational practice” – each made up of 6 to 11 related items. The five clusters are: level of academic challenge, active and collaborative learning, student-faculty interaction, enriching educational experiences, and supportive campus environment (Kuh, 2001). A number of other scales more focused on particular engagement areas were also employed: reading and writing, quality of relationships, institutional emphases on good practices, higher-order thinking, student-faculty interaction concerning coursework, and integration of diversity into coursework. Appendix A.1 lists specific survey items that contributed to each scale and provides reliability coefficients. In some instances, there is overlap between items in these scales and the five clusters of effective educational practice (Appendix A.2). We also explored relationships between academic performance measures and self-reported gains associated with attending college in three areas: (1) general education, (2) personal and social development, and (3) practical competence. Finally, we probed the possible link between student engagement and satisfaction with their collegiate experience at their present institution. Descriptions and summary statistics for measures of academic performance, student engagement, and self-reported outcomes are presented in Table 1.

[Insert Table 1 about here]

Analytic Strategy

RAND and GRE test scores were standardized by converting each to an SAT metric. The standardization was performed by converting the RAND and GRE scores to distributions that

had the same mean and standard deviation as the students' SAT scores. To facilitate direct comparisons of GPA across students from different institutions (and to adjust for possible differences in grading standards across institutions), the GPAs within a school were converted to a score distribution that had the same mean and standard deviation as the SAT scores at that school. Once RAND, GRE, and GPA measures were standardized to the SAT scale, we tested the relationships between various student engagement measures and academic performance. We also juxtaposed self-reported gains and satisfaction from the NSSE – what some consider to be meaningful outcomes in their own right (Shulman, 2002) – with measures of student engagement.

We attempted to tease out conditional effects of student engagement on performance by examining these effects for students of different classes, ability levels (as measured by the SAT), sexes, races/ethnicities, fraternity or sorority affiliation, and transfer status, any of which might arguably affect student learning. Searching for conditional effects is important, because it is likely that the impact of college on student learning and personal development will be underestimated if conditional effects are neglected (Pascarella & Terenzini, 1991, 2005).

In an attempt to parse out precollege academic level, we statistically controlled for students' total SAT score in most analyses. We also controlled for a host of student demographic variables and collegiate experiences that could reasonably influence learning as well as student engagement: class, gender, residence, enrollment status, race/ethnicity, number of parents with a bachelor's degree or higher, major field, amount of unassigned reading, commute time, time spent caring for dependents, and hours worked off campus. We did this to more accurately isolate possible effects of student engagement on "learning" as represented by the RAND, GRE, and GPA measures.

The literature on student learning is replete with concerns about regression-based analyses to assess change in an outcome over time (Baird, 1988; Cronbach & Furby, 1970; Pascarella & Wolniak, 2004; Pike 1992, 2004), especially attempts to attribute changes in a given outcome to a particular experience such as participation in a program or involvement with an organization. In particular, standard approaches to measure change such as gain scores, residual scores, and repeated measures are notoriously unreliable (Baird, 1988; Pike 1992). Many of these so-called “value added” studies rely on the measurement of the outcome at more than one point in time, a minimum of a “pretest” and a “posttest.” With the exception of total SAT score, our data are cross-sectional in nature, in that initial “pretest” measures of RAND, GRE, or GPA at college entrance were not available. In that sense, ours is not a study of changes in student performance over time. However, because we can use total SAT as a control variable, and because SAT is correlated at .48 and .55 with RAND and GRE scores, respectively, we are able to explain substantial portions of the variance on RAND and GRE scores with the SAT score, rendering the unexplained portion to potentially be attributed to the net effect of student engagement. Following the lead of Pike (2004), the central aim of our study is whether students with identical SAT scores (and other student characteristics) but different engagement levels exhibit different learning outcomes. Finally, despite statistically controlling for many student characteristics, this effort – as with all non-experimental research – cannot eliminate the possibility that an unmeasured variable may confound the patterns reported here.

An earlier study using these data reported that students at certain institutions had higher RAND and GRE scores than would be expected given the typical relationship of these scores with their SAT scores (Klein et al., in press). This finding suggests that, relative to other participating institutions, certain colleges added more value than others in our sample. Within

this study, we consider the possibility that student engagement is a key process by which institutions add value for their students. Indeed, institutions may differ in their learning productivity, or how effectively they convert student engagement into learning outcomes (Kuh & Hu, 2001). We examined each institution's partial correlations between student engagement measures and academic performance to determine whether students at particular institutions realized more or less academic payoff from their engagement in effective educational practices. We ranked institutions according to the strength of the associations between engagement and learning, categorizing them as high, mid-range, or low in terms of learning productivity. We then regressed each performance measure on each engagement scale, the institution's learning productivity score (converting engagement into learning outcomes), and an interaction term between engagement and learning productivity.

One drawback to using the student as the unit of analysis when estimating institutional differences is that standard errors will be biased too small, increasing the chance that coefficients will be statistically significant (Raudenbush & Bryk, 2002). Thus, we relied on effect sizes to gauge whether institutional differences on fostering favorable engagement-performance linkages were substantively important. Should comparable data become available involving a greater number of institutions, future researchers should investigate institutional effects with multilevel modeling techniques (Raudenbush & Bryk, 2002).

Results

Relationships among RAND, GRE, GPA, and SAT

RAND and GRE scores correlated with total SAT at .48 and .55, respectively, indicating a healthy relationship between where a student falls in the SAT distribution and where they fall in the RAND and GRE distributions. Among first-year students, RAND and GRE scores

correlated with SAT scores at .52 and .54, respectively. Among seniors, RAND and GRE scores correlated with SAT scores at .38 and .46, respectively. The drops in both RAND-SAT (.52 to .38) and GRE-SAT (.54 to .46) correlations between the first and senior years suggest that institutions may influence student learning in the areas covered by these tests. There are, of course, other explanations, such as the effect of different grading standards across different academic majors. A curvilinear specification between RAND and SAT (but not GRE and SAT or GPA and SAT) yielded a better-fitting model than a linear one. Specifically, higher SAT scores were related to higher RAND scores only up to an SAT score of 1,434 – at which point higher SAT scores yielded slightly declining RAND scores. However, this inflection point is very high – only about 7 percent of the students tested had scores above 1,434. Finally, RAND and GRE scores correlated at .28 and .27 respectively with GPA. Controlling for SAT resulted in partial correlations of .18 and .15 for RAND-GPA and GRE-GPA, respectively.

Student Engagement Scales and Academic Performance

Table 2 presents bivariate and partial correlations between student engagement scales, RAND, GRE, and GPA measures, and self-reported outcomes. As shown in Table 2, we found a number of small but statistically significant positive correlations between student engagement and scores on the RAND and GRE tests, both before and after controls were added for a host of student characteristics. Level of academic challenge, supportive campus climate, reading and writing, quality of relationships, institutional emphases on good practices, and general education gains yielded positive partial correlations with RAND of .10 or greater (Column 2). None of the 15 partial correlations with RAND scores was negative. RAND scores had somewhat higher partial correlations with engagement and self-reported outcomes (Column 4) than did GRE scores, but there were no statistically significant negative partial correlations with GRE scores.

Reading and writing and gains in practical competence were correlated with GRE at .16 and .13, respectively.

[Insert Table 2 about here]

Student Engagement and GPA

Columns 5 and 6 of Table 2 show that levels of student engagement were often positively related to GPA. Very modest but statistically significant positive partial correlations (Column 6) were found for 9 of the 11 engagement scales: level of academic challenge (.07), active and collaborative learning (.13), student-faculty interaction (.13), supportive campus climate (.08), reading and writing (.06), quality of relationships (.08), institutional emphases on good practices (.07), student-faculty interaction concerning coursework (.10), and integration of diversity into coursework (.07). In addition, significant positive correlations were noted between self-reported outcomes and GPA: general education gains (.12) and personal-social gains (.11). *None* of the 15 scales examined were negatively correlated with GPA. These relationships are almost certainly understated due to the lagged nature of cumulative rather than current semester GPA. Overall, the relationships between the NSSE scales, GPA, RAND, and GRE scores were comparable in strength.

In a separate analysis not shown here in tabular format, models that regressed RAND, GRE, and GPA on student characteristics, including total SAT, explained about 32% percent of the variance in RAND, 37% of the variance in GRE, and 13% of the variance in GPA. Using the results from these three student-level OLS regression models, we computed residuals for each student. These residual scores represented the amount of student over- or underperformance relative to predicted scores, with negative residuals denoting that a student underperformed relative to similar counterparts in the sample. We then entered the residuals for RAND, GRE,

and GPA as dependent variables, and inserted a block of 11 student engagement measures (see Table 1) as predictors into each of the three equations. These 11 engagement measures explained 2.9, 1.3, and 3.1 percent of the variance in the residuals for RAND, GRE, and GPA, respectively. When entered into the model separately, the most powerful predictors of RAND residuals were supportive campus environment (1.8 percent), quality of relationships (1.8 percent), institutional emphases on good practices (1.0 percent), and reading and writing (.8 percent).

Student Engagement Items and RAND

To probe even further into the specific forms of engagement associated with higher academic performance, we computed partial correlations between RAND and individual items on the NSSE survey for first-year students and seniors. Many of these items were included in the 15 scales presented in Table 1, but others were not. Table 3 reports only those partial correlations that achieved statistical significance for one or both classes.¹ The largest positive correlations for first-year students (Column 1) were for the number of papers of fewer than 5 pages (.17), came to class having completed readings and assignments (.16), quality of relationships with faculty (.16) and administrative personnel and offices (.16), and worked harder than you thought you could to meet instructors' expectations (.14). The only significant and negative correlation between engagement and RAND for first-year students involved having serious conversations with students who were very different from you (-.14). While correlations between self-reported outcomes and RAND were generally positive, gains with respect to understanding people of other racial and ethnic backgrounds were negatively related (-.15). Correlations for seniors (Column 2) yielded several differences. In particular, seniors appeared

¹ Three institutions were dropped from this subanalysis by class, because their students' classes were measured differently, i.e., a semester prior to completion of *The Report* rather than during the same term. However, the inclusion of these three schools did not appreciably alter the patterns reported here by class.

to benefit less than first-year students from working harder, coming to class more prepared, preparing drafts of papers, writing more small papers, and having high quality relationships with collegiate employees. In contrast, seniors benefited more from working with other students on projects during class, integrating ideas from different courses, receiving high quality academic advising, and being at institutions that emphasize contact among students of different backgrounds, as well as attendance of campus events and activities.

[Insert Table 3 about here]

Conditional Effects of Pre-college Ability

We examined the linkages between student engagement, RAND, GRE, and GPA measures, and self-reported outcomes for those who scored in the lowest and highest quintiles of the SAT distribution. The lowest quintile included those who scored below 1,030 on the SAT, while the highest quintile consisted of those who scored greater than 1,330. Table 4 presents partial correlations between student engagement, academic performance, and self-reported outcomes for both the low ability and high ability groups – those who scored in the lowest quintile and highest quintile on the SAT, respectively. The results suggest that low ability students benefited more from engagement than high ability counterparts, particularly in terms of their RAND and GRE scores, and to a lesser extent, their GPA.

Column 1 displays correlations between student engagement and RAND scores for low ability students. Low ability students appeared to receive the greatest payoffs from quality of relationships (.26), a supportive campus climate (.23), integration of diversity into coursework (.20), student-faculty interaction concerning coursework (.18), and reading and writing (.18). In addition, gains in general education (.19) were significantly correlated with RAND scores for this group. In contrast, high ability students benefited considerably less than their low ability

counterparts in that none of the 15 correlations presented in Column 2 were significant and positive, and the majority were negative. This pattern generally persists for GRE scores in Columns 3 and 4, yet the differences between low and high ability students diminishes somewhat in Columns 5 and 6 for GPA. Taken as a whole, these findings suggest that institutional interventions to boost student engagement may have the greatest payoff for those most at-risk for leaving college prematurely.

[Insert Table 4 about here]

One interpretation of the different payoffs on RAND tests for students of different abilities might be that the RAND tests tap general intellectual ability to a large degree. Highly intelligent students may simply require less effort to achieve similar academic results. This might explain the large number of modestly negative correlations for high ability students. We find some evidence to support the notion that high ability students need to expend less effort in college to do well on the RAND tests. Although the correlation between scores on the RAND tasks and the amount of reading and writing students do in college was the strongest of the 15 correlations reported for high ability students (.09), it was still less than that for low ability students (.18). In supplementary analyses not shown in Table 4, we found that low ability students had a .17 correlation between total time spent preparing/studying for class and RAND score, while high ability students sported a correlation of only .01. Similarly, working harder than you thought you could to meet instructors' expectations was correlated at .13 ($p=.09$) with RAND score for low ability students, and only at .01 for high ability students.

Of particular interest is that the low ability group appears to benefit disproportionately from perceptions of a nurturing environment, such as a supportive campus climate and high quality relationships. Because this finding is consistent with the research on student retention

(Pascarella & Terenzini, 1991, 2005; Tinto, 1993), perhaps the apparent conditional effect of student ability is simply an artifact of selection processes, in that many alienated low ability students had already left institutions by this time. However, our data do not support the differential selection hypothesis. Restricting the analysis to first-year students of low ability, before the greatest risk of drop-out has occurred, continued to yield positive correlations with scores on the RAND tasks: supportive campus environment (.23) and quality of relationships (.10).

Other Conditional Effects. Earlier we reported some differential effects for first-year students and seniors (Table 3). We also tested whether engagement led to differential effects on RAND tests for women and men, whites and nonwhites, native and transfer students, and students with Greek organizational affiliations. A series of multivariate regression analyses did not reveal conditional effects for any of these measures except for level of academic challenge, which favored women. Further, we found little evidence of conditional effects by gender *within* particular institutions.

Institutional Differences

Klein et al. (in press) reported that students at some institutions had higher RAND and GRE scores than would be expected given the typical relationship of these scores with their SAT scores. This finding suggests that, relative to other participating institutions, certain colleges added more value than others. A final aim of our study was to determine if different institutions more effectively converted student engagement into academic performance, as measured by RAND tests. To this end, we examined the partial correlations within each institution, controlling for a curvilinear specification of SAT. Three institutions (a liberal arts college, a general liberal arts college, and a HBCU) had a large number of substantial positive associations

between engagement and RAND performance, while the majority had few or none. Three institutions exhibited many negative relationships (two master's level universities and one doctoral extensive university). To determine whether these observed within-institution differences were statistically significant, we conducted multivariate regressions that included an interaction term between each engagement scale and a dummy variable that was coded as "1" if the student was from one of the three institutions identified as the most effective at promoting favorable engagement-performance linkages, and "0" if the student was at an institution that promoted the least favorable or even detrimental engagement-performance linkages. Table 5 displays interaction terms if the interaction coefficient achieved statistical significance at the .05 level.

[Insert Table 5 about here]

Table 5 shows the statistically significant differences between students at the highest and lowest schools in the learning productivity distribution. An effect size (ES) was calculated for each scale if the interaction coefficient was significant. Initially, fully-standardized coefficients were computed for the most and least effective institutions, then the absolute difference calculated to yield the boost in RAND scores (in standard deviation units) accruing to a standard deviation increase in student engagement within most versus least effective institutions. As compared institutions in the lowest learning productivity groups, institutions in the highest learning productivity group were more able to convert 8 of the 11 engagement scales into higher scores on the RAND tests:

- level of academic challenge (ES=.22)
- student-faculty interaction (ES=.25)
- supportive campus environment (ES=.29)
- reading and writing (ES=.12)
- quality of relationships (ES=.24)
- institutional emphases on good practices (ES=.20)

- higher-order thinking (ES=.24), and
- student-faculty interaction concerning coursework (ES=.27)

Another way to interpret these findings – given that the overall standard deviation for the RAND test was 177.55 (Table 1) – is that each standard deviation increase in level of academic challenge is linked to an additional 39 point boost ($.22 * 177.55$). Moreover, the highest learning productivity institutions had significantly stronger relationships between RAND and student-reported outcomes (general education gains [ES=.29], personal-social gains [ES=.27], practical competence gains [ES=.20], and satisfaction [ES=.15]).

We also contrasted the top three institutions in terms of learning productivity with the eight institutions that performed near the middle of the sample, this latter set of schools included several selective liberal arts colleges, two master’s level universities, and one moderately selective doctoral degree-granting university (Table 6). As expected, we found fewer statistically significant interaction coefficients than in Table 5, even though the larger Ns at the student level (738 to 760 rather than 361 to 378) afforded additional statistical power. Even so, the institutions that appeared to perform the best were somewhat more effective at converting student-faculty interaction (ES=.12), enriching educational experiences (ES=.13), supportive campus environment (.09), reading and writing (ES=.05), quality of relationships (ES=.08), and student-faculty interaction concerning coursework (ES=.10) into greater RAND scores.

[Insert Table 6 about here]

In supplementary analyses not shown in tabular format, we found little evidence of varied institutional effectiveness for the GRE. However, this finding is based only on the six institutions that had sufficient numbers of students who completed the GRE tests. With respect to GPA, four institutions (HBCU, one selective liberal arts college, two master’s level

institutions (one public, one private) appeared to more effectively convert student engagement into higher grades.

Conclusions

On balance, the results of this study corroborate what many other researchers have found: that student engagement is linked positively to desirable learning outcomes such as critical thinking and grades. Although the relationships between engagement and academic performance were not as robust as we might hope, they were more conclusive than those reported by Ewell (2002). To the degree that student experiences, engagement, and academic performance change over the course of a collegiate career (and there is considerable evidence suggesting that this is so), the asynchrony in data collection points likely accounts for the inconclusive patterns found in the South Dakota data.

Our findings along with others (Ewell, 2002; Klein et al., in press; Pascarella & Terenzini, 2005) underscore the fact that learning outcomes stem from a variety of sources, of which student engagement is only one. Indeed, the positive relationships between engagement and outcomes described in this paper are relatively small in magnitude. A large portion – and in some cases a majority – of the variance in key outcomes remains to be explained by yet undiscovered factors. We hope to learn more about the relationships between student engagement and learning from a Pew-sponsored National Forum on College-Level Learning project that co-administered NSSE, RAND, and the National Assessment of Adult Literacy at about 50 colleges and universities in 2003-2004.

In addition to the generally positive but relatively weak effects of engagement on critical thinking skills, the NSSE-RAND analyses point to two evocative findings. First, college students with the lowest SAT scores appeared to benefit more from student engagement than

those with the highest SATs. While this pattern dovetails with some recent research, we cannot rule out that these findings may be in part attributable to ceiling effects or the phenomenon of regression to the mean. A future study might use multiple measures to control for student ability prior to matriculation to increase their stability. Such a strategy would decrease the probability that the very lowest or highest measures of pre-college ability were due to chance or unusual circumstances unlikely to repeat at a later measurement point.

Second, using these same data, Klein et al. (in press) suggested that certain institutions appear to add more value than others, as measured by the RAND critical thinking tests. Our analysis indicates that certain institutions more effectively convert engagement into stronger student performance as represented by RAND scores. Thus, the findings suggest that student engagement constitutes a constellation of institutional processes that may “add value” to student learning. Although this study is based on only 14 institutions, institutional differences were discernable, particularly between institutions most and least effective in converting student engagement into performance. It would be instructive to conduct intensive case studies of high performing institutions to learn what they do or have that seem to contribute to greater student learning productivity, i.e., to extend the work of Kuh, Schuh, Whitt and Associates (1991) and Kuh, Kinzie, Schuh, Whitt and Associates (2005).

In closing, it is important to note that we were able to examine the complex relationships between engagement and learning outcomes only because we were able to analyze student-level data across multiple institutions. The integration of multiple measures (SAT scores, RAND/CAE scores, grades, student engagement results from NSSE) was made possible by the cooperation of the participating colleges and different research teams. Such efforts are few and

far between. The results of this study illustrate the insights that can accrue from such collaborative research endeavors.

Table 1. Means, Standard Deviations and Descriptions for Academic Performance, Student Engagement Scales, and Self-reported Outcomes

Measure	Description	Metric	Mean	SD	N
<i>Academic Performance</i>					
RAND Test Score	Composite performance and critical thinking score	Standardized to SAT distribution	1,186.13	177.55	940
GRE Test Score	Composite GRE prompt score	Standardized to SAT distribution	1,120.93	157.77	506
GPA	Cumulative college grade point average	Z-scored to within school distribution	.02	.98	1,004
<i>Student Engagement</i>					
Level of academic challenge	Nature and amount of academic work performed	Sum of 11 items	18.98	4.33	1,034
Active and collaborative learning	Frequency of class participation and collaborative learning	Sum of 7 items	10.51	3.35	1,045
Student-faculty interaction	Frequency of student interactions with faculty	Sum of 6 items	8.43	3.85	1,043
Enriching educational experiences	Degree of participation in educationally fruitful activities	Sum of 11 items	6.55	1.75	1,023
Supportive campus climate	Degree to which the institution is perceived to be supportive	Sum of 6 items	11.12	3.08	1,049
Reading and writing	Amount of assigned reading and writing	Sum of 3 z-scored items	-.001	2.25	1,052
Quality of relationships	Quality of your relationships with people at your institution	Sum of 3 items	16.21	2.84	1,054

[Table 1 continued next page]

Table 1 (continued). Means, Standard Deviations and Descriptions for Academic Performance, Student Engagement Scales, and Self-reported Outcomes

Measure	Description	Metric	Mean	SD	N
<i>Student Engagement (continued)</i>					
Institutional emphases on good practices	Degree institution perceived to uphold good practices	Sum of 5 items	13.15	3.32	1,047
Higher-order thinking	Frequency higher-order skills included in coursework	Sum of 4 items	12.43	2.51	1,052
Student-faculty interaction concerning coursework	Degree of interaction involving coursework	Sum of 3 items	7.94	1.97	1,051
Integration of diversity into coursework	Degree coursework involved diverse perspectives and ideas	Sum of 5 z-scored items	-.01	3.39	1,046
<i>Self-reported Outcomes</i>					
Gains: general education	Self-reported gains in writing, speaking, and thinking critically	Sum of 4 items	8.42	2.50	1,053
Gains: personal and social	Self-reported gains related to personal and community issues	Sum of 7 items	12.02	4.38	1,048
Gains: practical competence	Self-reported gains related to job-related skills	Sum of 4 items	7.53	2.53	1,051
Satisfaction	Degree satisfied with institution	Sum of 2 items	6.50	1.35	1,053

Appendix A.1: Survey Items Contributing to Student Engagement and Self-reported Outcome Scales

I. Level of Academic Challenge (Cronbach's alpha=.70)

- Item 1. Number of hours per week spent on preparing for class (studying, reading, writing, rehearsing, and other activities related to your academic program)
2. Frequency worked harder than you thought you could to meet instructors' standards or expectations during the current school year
 3. Number of assigned textbooks, books, or book-length packs of course readings during the current school year
 4. Number of written papers or reports of 20 pages or more during the current school year
 5. Number of written papers or reports between 5 and 19 pages during the current school year
 6. Number of written papers or reports of fewer than 5 pages during the current school year
 7. During the current school year, the extent coursework emphasized analyzing the basic elements of an idea, experience, or theory
 8. During the current school year, the extent coursework emphasized synthesizing and organizing ideas, information, or experiences into new, more complex interpretations and relationships
 9. During the current school year, the extent coursework emphasized making judgments about the value of information, arguments, or methods
 10. During the current school year, the extent coursework emphasized applying theories or concepts to practical problems or in new situations
 11. The extent the institution emphasized spending significant amounts of time studying and on academic work

II. Active and Collaborative Learning (Cronbach's alpha=.62)

- Item 12. Frequency asked questions in class or contributed to class discussions during the current school year
13. Frequency made class presentations during the current school year
 14. Frequency worked with other students on projects during class during the current school year
 15. Frequency worked with classmates outside of class to prepare class assignments during the current school year
 16. Frequency tutored or taught other students (paid or voluntary) during the current school year
 17. Frequency participated in a community-based project as part of a regular course
 18. Frequency discussed ideas from your readings or classes with others outside of class (students, family members, coworkers, etc.) during the current school year

III. Enriching Educational Experiences (Cronbach's alpha=.56)

- Item 19. Frequency used an electronic medium (list-serv, chat group, Internet, etc.) to discuss or complete an assignment
20. Frequency had serious conversations with students of a different race or ethnicity than your own
 21. Frequency had serious conversations with students who differed from you in terms of their religious beliefs, political opinions, or personal values
 22. Have done or plan to complete a practicum, internship, field experience, co-op experience, or clinical assignments
 23. Have done or plan to do community service or volunteer work
 24. Have done or plan to take foreign language coursework
 25. Have done or plan to study abroad
 26. Have done or plan to complete an independent study or self-designed major
 27. Have done or plan to complete a culmination senior experience (comprehensive exam, capstone course, thesis project, etc.)
 28. Number of hours per week participated in co-curricular activities (organizations, campus publications, student government, social fraternity or sorority, intercollegiate or intramural sports, etc.)
 29. The extent the institution emphasized contact among students from different economic. Social, and

racial or ethnic backgrounds

IV. Student Interactions with Faculty Members (Cronbach's alpha=.71)

- Item 30. Frequency discussed grades or assignments with an instructor during the current school year
31. Frequency talked about career plans with a faculty member or advisor during the current school year
 32. Frequency discussed ideas from your readings or classes with faculty members outside of class during the current school year
 33. Frequency worked with faculty members on activities other than coursework (committees, orientation, student life activities, etc.) during the current school year
 34. Frequency received prompt feedback from faculty on your academic performance (written or oral) during the current school year
 35. Have done or plan to work on a research project with a faculty member outside of course or program requirements

V. Supportive Campus Environment (Cronbach's alpha=.75)

- Item 36. The extent the institution emphasized providing the support you need ed to succeed academically
37. The extent the institution emphasized helping you cope with non-academic responsibilities (work, family, etc.)
 38. The extent the institution emphasized providing the support you needed to thrive socially
 39. Quality of Relationships with other students at your institution
 40. Quality of Relationships with faculty members at your institution
 41. Quality of Relationships with administrative personnel and offices at your institution

VI. Reading and Writing (Cronbach's alpha=.61)

- Item 3. Number of assigned textbooks, books, or book-length packs of course readings
5. Number of written papers or reports between 5 and 19 pages
 6. Number of written papers or reports of fewer than 5 pages

VII. Quality of Relationships (Cronbach's alpha=.60)

- Item 39. Quality of Relationships with other students at your institution
40. Quality of Relationships with faculty members at your institution
 41. Quality of Relationships with administrative personnel and offices at your institution

VIII. Institutional Emphases on Good Practices (Cronbach's alpha=.78)

- Item 29. The extent the institution emphasized contact among students from different economic, social, and racial or ethnic backgrounds
36. The extent the institution emphasized providing the support you need ed to succeed academically
 37. The extent the institution emphasized helping you cope with non-academic responsibilities (work, family, etc.)
 38. The extent the institution emphasized providing the support you needed to thrive socially
 42. The extent the institution emphasized the attendance of campus events and activities

IX. Higher-Order Thinking (Cronbach's alpha=.74)

- Item 7. During the current school year, the extent coursework emphasized analyzing the basic elements of an idea, experience, or theory
8. During the current school year, the extent coursework emphasized synthesizing and organizing ideas, information, or experiences into new, more complex interpretations and relationships
 9. During the current school year, the extent coursework emphasized making judgments about the value of information, arguments, or methods
 10. During the current school year, the extent coursework emphasized applying theories or concepts to practical problems or in new situations

X. Student-Faculty Interaction Concerning Coursework (Cronbach's alpha=.68)

- Item 30. Frequency discussed grades or assignments with an instructor during the current school year
- 32. Frequency discussed ideas from your readings or classes with faculty members outside of class during the current school year
 - 34. Frequency received prompt feedback from faculty on your academic performance (written or oral) during the current school year

XI. Integration of Diversity into Coursework (Cronbach's alpha=.71)

- Item 8. During the current school year, the extent coursework emphasized synthesizing and organizing ideas, information, or experiences into new, more complex interpretations and relationships
- 32. Frequency discussed ideas from your readings or classes with faculty members outside of class
 - 43. Frequency worked on a paper or project that required integrating ideas or information from various sources
 - 44. Frequency included diverse perspectives (different races, religions, genders, political beliefs, etc.) in class discussions
 - 45. Frequency put together ideas or concepts from different courses when completing assignments or during class discussions

XII. Gains in General Education (Cronbach's alpha=.77)

- Item 46. The extent your college experience contributed to writing clearly and effectively
- 47. The extent your college experience contributed to speaking clearly and effectively
 - 48. The extent your college experience contributed to acquiring broad general education
 - 49. The extent your college experience contributed to thinking critically and analytically

XIII. Gains in Personal and Social Development (Cronbach's alpha=.80)

- Item 50. The extent your college experience contributed to developing a personal code of values and ethics
- 51. The extent your college experience contributed to understanding people of other racial and ethnic backgrounds
 - 52. The extent your college experience contributed to understanding yourself
 - 53. The extent your college experience contributed to learning effectively on your own
 - 54. The extent your college experience contributed to working effectively with others
 - 55. The extent your college experience contributed to acquiring broad general education
 - 56. The extent your college experience contributed to thinking critically and analytically

XIV. Gains in Practical Competence (Cronbach's alpha=.66)

- Item 57. The extent your college experience contributed to acquiring job or work-related knowledge and Skills
- 58. The extent your college experience contributed to analyzing quantitative problems
 - 59. The extent your college experience contributed to using computing and information technology
 - 60. The extent your college experience contributed to (your) working effectively with others

XV. Satisfaction (Cronbach's alpha=.75)

- Item 61. How would you evaluate your entire educational experience at this institution?
- 62. If you could start over again, would you go to the same institution you are now attending?
